## Canadää

## Acknowledgments

A study of this sort could not be carried out without the assistance of many people. I wish to thank all the principals, teachers, and parents who gave permission for the testing, the students who participated, and those who assisted me. Particular thanks are due to Lisa Labelle who volunteered many hours of her time to assist me in collecting the data.

I gratefully acknowledge the excellent help of my supervisors, Dr. M.A. Mountain, and Dr. C. Netley who gave excellent suggestions and continued support. Dr. John Jamieson gave graciously of his time to suggest remedies for statistical problems. Last, but not least, my husband deserves much credit for his continued love and never-failing encouragement even when progress on this thesis meant hasty meals and forgotten laundry. To all of you, a deeply felt THANK YOU.

## Abstract

The purpose of this study was to develop a measure of children's copying speed (conditions: making $X$ 's in boxes, copying unfamiliar alphabet-like figures, writing pronounceable nonsense syllables, and copying grade appropriate paragraphs from the Gray Oral Reading Tests presented as desk copy or board copy) and copy span. Four hundred twenty-five children in grades 2 through 8 were tested. It was found that copy speed and copy span increased with age and grade, that the relative speed of the tasks varied between grades, and that girls were faster than boys on tasks involving alphabet letters. The Copy Speed and Span Test is a reliable measure of children's copy speed and span that should be useful in future research.

With the advent of computers and photocopiers handwriting appeared to be a skill that would soon become obsolete. Now, however, despite growing use of both machines, we realize that it is unrealistic to imagine a world where one must carry a computer around to jot down notes. Even battery operated machines have a limited range from a source for recharging. A pencil stub and sheet of paper can fit compactly into a pocket or purse, to be used whenever needed. Distributing to students the vast amounts of information currently required while trying to deal with cutbacks in funding, schools are finding that a reversion to the old "copy it off the board" methods can save them money. Handwriting still has a place in our lives. It is also likely that the easier it is for us to get our thoughts written down, the more likely that we will use handwriting regularly. Fast writing seems to be associated with more mature syntactical structure in written work (McAndrew, 1990), something all teachers hope to see their students
develop.
Children who must copy work into their notes must be able to get all the material copied before the board is erased. If they fail, they have incomplete notes and nothing from which to study for examinations. Often children do such poor written work that they are told they must copy it over. Thus they must spend hours of extra time re-copying work. Many children seem to find themselves in this position. Parents and teachers wonder what is wrong.

While a number of investigators have looked at the subject of handwriting speed, there has been little uniformity in conditions of measurement. Some school psychologists have expressed a need for a method of determining a student's level of achievement in handwriting speed. Teachers often describe a student as a "slow writer", but without a scale based on uniform conditions of measurement one cannot make clinically valid interpretations. The conditions of measurement are also important in understanding why one investigator's results may differ from another's results.

The problem of uniform conditions of measurement has been recognized previously in the literature. Ziviani
(1984) examined the methods of previous studies and compared the resulting speeds with her own findings. These speeds are shown in Table 1. It is readily apparent that there are large discrepancies. [All speed scores in this paper have been reported in or transformed to letters per minute (lpm) to facilitate comparison.]

| Table 1. | Mean | Handwriting | Speed in Letters/Minute*: |  |
| :--- | :---: | :---: | :---: | :---: |
| Grade | $\frac{1912}{--}$ | $\frac{1954}{40}$ | $\underline{1961}$ | $\frac{1984}{--}$ |
| 4 | 55 | 50 | 35.06 | 32.60 |
| 5 | 64 | 60 | 40.65 | 38.24 |
| 6 | 71 | 67 | 49.60 | 46.41 |
| 7 | -- | 74 | -- | 52.15 |

[^0]Other writers have reported their measurements of copy speed. Sometimes it is reported as an "extra" bit of information in a study that is investigating something else. The copy speeds reported in these studies is summarized in Table 2. Again, discrepancies are apparent.

Table 2. Other Reports of Handwriting Speed
Grade Klein Otto \& Jackson Zaner-Bloser (1979)
(1979) Rarick (1970) [from Reis, 1989] (1968)

| 1 |  | - |  | 25 |
| :---: | :---: | :---: | :---: | :---: |
| 2 | - | - | - | 30 |
| 3 | - | - | - | 38 |
| 4 | 35.84 | 37.6 | $1-36.55$ | 45 |
|  |  |  | $2-60.16$ |  |
| 5 |  |  | $1-50.43$ | 60 |
| 6 | 52.26 | 53.6 | $1-71.03$ |  |
|  |  |  | $2-77.73$ | 67 |
| 7 | - |  | - |  |
| 8 | 77.00 |  | - | 74 |
|  |  |  |  | - |

The importance of measurement conditions can be seen in Jackson's results. Jackson had two conditions: (1) "as well and as rapidly as you can", and (2) "as fast as you can". Lawton \& Currie (1980) give sample speed norms which match Freeman's rates but add 80 lpm as a goal for grade 8 students. They give no data about where or how the norms were obtained. Sawyer, Francis \& Knight (1992) give the mean for Year 10 pupils as 107.39 lpm with a range from 85 lpm for the all male, low ability band to 122.95 for the mixed sex, high ability band. College students were reported by Gust and Schumacher (1969) to have a mean rate of $126-128 \mathrm{lpm}$.

These varying speed scores reflect the differences
in conditions and materials employed in the various studies. Table 3 presents a summary of these important factors.

Table 3. Conditions/Materials Used in Writing Speed Studies

| Author | $\underline{n}$ | Model | Location | PracticeType/Amt |
| :---: | :---: | :---: | :---: | :---: |
| Ayres | class | Gettysburg Address | Board | Written/Repeated |
| Freeman | ? | , | Board | Written/Repeated |
| Groff | 4834 | " " | Board | Read/Repeated |
| Ziviani | 575 | "cats and dogs" | Desk | None |
| Klein | 194 | grade 7 <br> level | Desk | None |

| Rarick |  | words |  |  |
| Jackson | 108 | .quick brown | $n$ ?? | ?? |

Sawyer,Francis 50 gov't exam Desk None \& Knight

The wide variation in conditions and materials is evident in Table 3. Some studies had the model on a chalkboard, others on the desk. Copying speed may differ when the material is copied from the board as compared to when it is copied from a paper on the desk. With longer distances for the eye to travel when the material is on the board, there is more chance that distracting stimuli will be encountered. Finding and focusing on a small target on a large background is also likely to increase the time involved. Therefore there are likely to be
differences in copying speed norms between the two tasks.

Practice type and amount are also likely to affect copying speed. Ayres (1912, in Groff, 1961) and Freeman (1954, in Ziviani, 1984) had students practice writing the passage over and over. Groff (1961), in contrast, had the students read the passage without writing it until they knew all the words. Klein (1979) and Sawyer, Francis and Knight (1992) used previously unseen material which would conceivably be closer to what would be encountered in the classroom.

Variation in difficulty levels in the model is also likely to result in differences in copying speeds. The Gettysburg Address is not simple. Yet Ayres' and Freeman's norms are used to evaluate speed when students are given simple material to copy. A phrase such as "cats and dogs" written repeatedly could likely be written from memory after the first time by most students. Thus it is not appropriate to compare speeds obtained from such copy with those obtained when the copy requires continuously looking back at the model.

The test-retest reliability of speed scores, after a period of two months has been reported to be . 85
(Mojet, 1991) indicating that performance consistency can be expected. While popular opinion appears to hold that cursive style handwriting is faster than manuscript style (printing), Jackson (1970) found that manuscript style writers in grades 5 and 6 were as fast as cursive style writers. Children's "best" work is better than their fast work (Harris \& Herrick, 1963) which implies that they write slower when they know they are being judged on quality. This finding alone may account for the differences in speeds found by different investigators. The emotional quality of the copy chosen does not seem to affect the speed at which the words are written. There was no significant difference between the speed at which pleasant words such as "pretty" or unpleasant words such as "murder" were written in Matlin and Kennedy's (1976) study.

Dyslexics write slower than "normals" (Whitehouse, 1983; Sovik, Arntzen \& Thygesen, 1987) though in a copying task their performance was more similar to their age mates than to younger children with the same spelling ability (Martlew, 1992) which would perhaps support a maturational component in copying speed. Hildreth (1947) asserted that maturation appeared to be a dominant factor
in handwriting speed. However, maturation may not be the complete explanation. Simner (1991) reported that children who had many form errors in printing in kindergarten later wrote more slowly than other children. Simner attempted to explain the slower writing as the result of a memory problem (the form fades) or as an organizational problem. Keele and Hawkins' (1982) work appears to support a personal motor speed factor. They found that the rate of repetitive activity is common across different muscle groups and that the rate of wrist, finger or foot tapping is related to and predicts handwriting speed. Greater speed may be related to higher intelligence (Love, 1965; Jackson, 1970; May \& Brannin, 1984).

Research on sex differences in handwriting speed strongly suggests that females are faster than males (Burt, 1921 in Bailey, 1988; Groff, 1963 in Andersen, 1965; Klein, 1979; Ziviani, 1984) although Jackson (1970) did not find differences. Judd, Siders, Siders and Atkins (1986) found that grade one boys were as fast as girls in placing dots in circles, but that they were significantly slower at copying symbols. They point out that the literature reports differences between the sexes
in older children and adults in fine motor and visuospatial tasks as well (though no direct comparison of the same task is reported). Since writing involves symbol copying, their work seems to support sex differences in handwriting.

Handedness does not seem to make a difference in speed in and of itself (Auzias, 1973; Herron, 1980). Athenes \& Guiard (1991) found that speed for left handed subjects was related to hand position and arm position in relation to the page. Left handed "inverters" wrote faster with the arm in a more horizontal position on the page. Left handed non-inverters wrote faster when the arm was more vertical on the page. For right handed subjects, speed did not seem to be affected by the amount of forearm slant on the page.

Other factors may also affect copying speed.
Furner (1969) argues that young students must be taught to perceive the stimulus carefully before they can be expected to copy it accurately. Then a child must remember what has been perceived long enough to get it copied. Visual and verbal memory seem to be separate entities (Woodhead \& Baddeley, 1981). Young children have greater dependence on visual working memory,
particularly when dealing with visually presented material although they do use phonological memory when working with material presented in the auditory mode. Older children, however, seem to depend more on phonological memory, translating visual material into phonological material which they can then rehearse (Hitch, Halliday, Schaafstal \& Schraagen, 1988). The introduction of auditory labels onto the copying task by the experimenter facilitates young children's ability to copy shapes (Stiles, Tada and Whipple, 1990). Berninger, Yates and Lester (1991), working with visual material, suggested that a child uses multiple orthographic codes and that the codes used will change as the child develops skills. How efficiently a child decodes and encodes the stimulus material in copying likely affects speed.

A child must therefore perceive the material to be copied, decode it and then encode it in memory in some way. Other requirements of efficient copying behaviour might be stores of motor programs, kinematic information, and spatial and temporal programs covering the details of which muscles to move to what extent in which direction, how fast or slow, and with how much force in order to accomplish the task (Laszlo and Broderick, 1985; Zimmer
and Engelkamp, 1985).
Copying span (the amount of material that can be clearly recalled immediately after it is no longer available to sight) is almost certainly a factor in copying speed. Mori and Yamada (1988) tested the relative contributions of copying span and copying speed in measuring written language ability in adult students of English as a second language. In their study they found that, while there were exceptions, generally people with short copy spans were poor readers and those with longer copy spans were good readers. Bradley (1983) reported that poor young readers tended to copy letter by letter and normal readers copied by words or phrases which would tend to support Mori and Yamada's findings. Spelling ability might also have been a factor. Rothkopf (1980) suggested that copying span is a function of the information burden of the material. These findings suggest that more attention should be paid to comparing copying span with copying speed in children to see how the two relate.

The findings of these previous studies and the questions raised by differences in their reported copy speeds lead to the following hypotheses in this study.

1. Based on speculation about the possible difficulty of copying tasks with varying degrees of complexity, familiarity, and distance involved it was hypothesized that speed would be greatest for making $X$ 's in boxes (a spatial-graphic, largely motor task), followed by writing words from desk copy (a practiced, semantic-lexical-phonologicalgraphic task with minimum space difference), followed by writing words from board copy (similar to desk copy but with the additional distance variable), followed by writing nonsense words (non-lexical-phonological-graphic task) followed by copying non-meaningful figures (an orthographic task).
2. Based on Furner's supposition that one must perceive the stimulus as a first step, it was hypothesized that the difficulties of perceiving a more distant model might cause copy from a board to be slower than copy from a desk model.
3. It was also hypothesized that, given the greater familiarity level of the material, copy speed would be greater when readability level of material was considerably lower than the students'
grade level.
4. Familiarity as well as the factor of physical maturation led to the hypothesis that copy speed and copy span would increase with age and grade.
5. Because of the time factor involved in looking back at a copy, it was hypothesized that greater copying speed would be expected for word copying (measured by the board task) in subjects with longer copying span (the number of recognizable words that can be written in response to a 5 second exposure to the stimulus material presented on the board) in the copy span task.
6. The findings of previous studies in the literature suggested the hypothesis that females would be faster than males in most tasks.

## Method

## Subjects

Students enroled in grades 2 through 8 in five elementary schools in and around a Northern Ontario city were approached for testing. The schools were chosen in consultation with a board of education in the district. Special attention was given to trying to use schools that
had students from a range of socio-economic levels. The selection was not a truly random sample, but was based on accessibility. The principals of schools 1, 3, and 4 asked for parental permission forms to be completed.

Poor parental response resulted in only portions of the classes being tested. Principals in the other two schools decided that the content was sufficiently academic and that participants were anonymous and so allowed the testing of entire classes if the classroom teacher agreed. In both of these schools all students of a particular grade were tested, thus assuring a representative sample was obtained. A total of 425 students were tested. As can be expected with such a large number, a few students did not cooperate. In some classes some students reported difficulty reading the overhead. Some students were observed looking at a neighbour's paper during the copy span task. Such students were noted by protocol number and their scores omitted from calculations that might be affected. The number from each grade tested and retained was as shown below:

| Grade | Number Tested |  | Number Retained |  | Retested |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Retested |  |
| 2 | 41 | 37 | 12 |  |  |
| 3 | 74 | 72 | 10 | 26 |  |
| 4 | 63 | 59 | 7 |  |  |
| 4 | 65 | 64 | 5 |  |  |
| 5 | 32 | 32 | 3 |  |  |
| 6 | 81 | 65 | 7 |  |  |
| 7 | 69 | 63 | 1 | 20 |  |
| 8 | 425 | 392 | 45 | 46 |  |

There were approximately equal numbers of male and female subjects overall (for exact numbers see Tables of Means for males and females in Appendices $F$ and G).

Research assistants
One volunteer assistant was available for helping in each large group. The assistant helped to distribute and collect materials, observed for compliance with instructions, observed writing postures, and recorded protocol numbers for distance from the board and problems such as noncompliance. Three assistants were trained and used.

## Measures

The Copy Speed and Span Test (CSAS) was constructed in an attempt to provide a uniform means of measuring copy speed and to determine some of the factors which contribute to it (see appendix B). Test forms were constructed to provide space for the five speed tasks and
the span task. They also contained space for students to record information on date, age, birthdate, grade, sex, and hand, eye, and foot preference. If left handed, students were asked whether they write with their hand above (inverted posture) or below their writing. An additional question asked whether the student reads or writes a language that uses different letters than English or French since familiarity with another alphabet might indicate familiarity with the supposedly "nonmeaningful" material.

Speed Tests. Five speed tests were devised.

1. X's. The motor (spatial-graphic) task consisted of marking $X$ 's in boxes. This task requires two strokes making it a better comparison with alphabet tasks than making dots. It does not require reading skills nor does it tax memory abilities. Therefore it was thought to be a good measure of motor speed.
2. Symbols. The non-verbal task consisted of copying generally unfamiliar symbols from the WordPerfect (1991) extended characters (see test form, Appendix B). These characters are used in other languages or specialized areas and most are similar in complexity (number of strokes or direction changes) to letters, but were
thought to be unfamiliar to most students studying in English in North American schools. For figures such as triangles which could be verbally labelled by most students, the orientation of the symbol still interfered with quick verbal labelling.
3. Nonsense syllables. A list of pronounceable nonsense syllables (see Appendix A) was used to test nonmeaningful copying ability.
4. Desk copy task. Two passages selected from the Gray Oral Reading Tests (GORT, Robinson, 1963) with equivalent reading level were used for each grade (see Appendix A). One of these passages was used for the desk copy task and the other for the board copy task. The difficulty level used in each grade was one level below the grade levels assigned by the GORT. It was anticipated that the choice of reading difficulty level would provide a control on relative difficulty of the task for each grade without making the task too far above slow readers in each grade. The 1963 version was used to avoid exposing current test materials to such a large group of students.
5. Board copy task. This task used the parallel paragraph from the Gray Oral Reading Tests (Robinson, 1963) selected for each grade that was not used in the
desk copy task. This ensured similar difficulty level in the two tasks but eliminated any familiarity effects. In the board task material was presented by overhead projector from approximately 8-10 feet from the screen (actual distances were dictated by physical arrangements in each classroom).
6. Extra. An extra paragraph, not part of the CSAS, with high grade $1 /$ low grade 2 readability (Fry, 1988) written by the experimenter (see Appendix A) was used in the pilot portion of the study (see procedure section) to assess the effects of readability level on copy speed. Students copied this paragraph onto standard notebook paper. This paragraph was given to all students in the pilot portion who were above Grade 3. Because of time constraints only one group of the pilot Grade 3 students copied the low readability level paragraph. (Because the Grade 3 and 4 students were deemed to be too close to the level of the low readability paragraph, and because they greatly outnumbered the older students in the pilot study, it was later decided to analyze only grade 5 and higher protocols in determining the effect of readability level on copy speed.)

Copy Span. The copy span materials consisted of
lines of randomly ordered words taken from the Dolch Word List (Dolch, 1960; see Appendix A) and presented by overhead projector for five seconds. The first two presentations for all grades were one line long and the last two for all grades were two lines long. The third presentation was one line long for lower grades and two lines long for upper grades. Students were given warning before being shown the first two line presentation, and assured that they did not have to worry if they could not read all the words in time. They just needed to remember as many as they could.

## Procedure

Approximately two to three weeks prior to the testing in each school that required parental permission, students were told of the experiment and given consent forms to sign and have their parents sign (see Appendix C). Two forms were used as the response rate with the first form was very low.

Pilot Study. A pilot study was conducted using all the students from School 1 whose parents had given permission. Since a ceiling effect was detected with the copy span task as originally designed (sentences), the task was changed to random words from the Dolch Word List
(Dolch, 1960) for the remaining classes.
Test-Retest. Students from School 1 were retested 26 days later to assess test-retest reliability of the speed tests (in which no problems were detected) and to administer the revised copy span measure. (For students in School 1, scores from the first testing were used in speed analyses and from the revised measure for copy span analyses.) Students from grades 3 and 8 in School 5 were retested 14 days later to assess test-retest reliability on the revised copy span measure. For all students retested matching of the original protocol with the retest protocol was done by birthdate and sex. Where there was a duplicate of birthdate and sex within the class, protocols were matched by comparing handwriting style using three independent judges. Teachers did not see the completed forms and the researcher did not have access to names.

Administration. Students first completed the demographic data on the test form and were allowed to use whatever style of writing and whatever writing implement they found most comfortable. Students were instructed to "Write as quickly as possible, but I must be able to read it." It was thought that this would approximate most
closely the classroom copying situations with which comparisons might be made. (See Appendix D for specific wording of instructions for each task.)

All students began with making $X$ 's in boxes. The task of making X's was thought to be the easiest task and thus to be suitable as a warm up. One of the complete schools then followed this order:
2. Non-verbal
3. Pronounceable nonsense syllables
4. Board copying task
5. Desk copying task
6. Copy span task

The other complete school did the tasks in the reverse order in order to provide some control for fatigue effects. Where classrooms contained two grades, desk and board copy tasks were run concurrently with one grade doing the desk task and the other the board task.

Stimulus materials for the non-meaningful characters were presented in the test booklet immediately above the square in which they were to be copied. Materials for the nonsense syllables and desk copy were presented on cards on the desk. Board and copy span task materials were prepared ahead (to keep model quality constant) and presented by overhead projector from as close to the same distance as physical conditions permitted for all classes
(approximately $8-10$ feet). All verbal materials were typed and made to resemble the original cards from The Gray Oral Reading Test (Robinson, 1963) as closely as possible in size and spacing.

Tests of X's, non-meaningful characters and nonsense syllables were timed for one minute. It was thought that to run these tests for two minutes, while it would have provided a better comparison with the desk and board copy tests, would have caused the test to become unnecessarily long. This might have created boredom and undue fatigue in the student while making teachers less willing to allow access to their classes. Tests of desk and board copying of words were timed for two minutes and the results divided by two to obtain the rate as this longer task more closely resembles classroom handwriting tasks where persevering with speed is important as well as earlier tests of speed such as Groff (1961). Each group of words for the copying span task was exposed for 5 seconds and then removed. Students began to write when the stimulus was removed and were given as long as needed to respond.

In the pilot stage the older classes were given an additional paragraph on a paper on the desk written by
the experimenter using a Fry (1988) readability index rating of high grade $1 / l o w ~ g r a d e ~ 2 ~ d i f f i c u l t y . ~ T h i s ~$ additional paragraph was used as the "very easy material" in comparing speeds with grade appropriate material (desk copy task).

The entire class time required was about 30 minutes (testing time about 12 minutes and the remainder for material handling and writing of demographic data). Whenever possible, students were tested in the regular classroom as a class in order to reproduce classroom writing conditions. If too few returned consent forms, those who did were removed to another room for testing in groups of 6 to 8 .

## Scoring

Scores were the number of letters, symbols, or X's per minute. All letters were counted without reference to quality or spelling. A separate count was made of errors and omissions.

Scoring criteria was as follows:
X's: Every pair of two lines was counted as "1". If one pair of crossed lines was superimposed on another within the same square, credit was given for two letters and one error. An error was counted if
lines did not intersect or have at least minimal evidence of a fourth extension or if neither line was minimally diagonal.

Symbols: Every completed square with a symbol was counted as "1". If parts of the symbol were missing or if it was rotated more than approximately 45 degrees an error was counted. Superimposed symbols counted as two symbols and one error.
Nonsense: Every letter counted as "1". Superimposed letters counted as two letters and one error. Incorrect letters were counted but also counted as errors. Every place where an omission occurred was counted as one omission regardless of the number of letters or words skipped.

Board and Desk: Same as nonsense.
Copy Span: Span was measured by the number of correct words written. For the copy span task any reasonable approximation was accepted and homonyms (words sounding the same but with different spelling and meaning) were counted as correct. No error count was made.

Results

## Reliability

Test-Retest. All analyses were done with the SPSS (version 4.0) statistical package. Test-retest reliability was calculated to ascertain whether speeds and spans recorded could be considered as representative scores for a subject. This is considered to be an acceptable method of determining reliability in speed tests (Murphy \& Davidshofer, 1988). Reliability was determined by correlations between the first and second testing. The results were all significant at the $\mathrm{p}<.01$ level as seen in Table 4:

Table 4. Test-Retest Correlations

| Subtest | Pearson's r |
| :--- | :---: |
| X's $^{\prime}$. | .9486 |
| Symbol | .8902 |
| Nonsense | .9689 |
| Desk Copy | .9735 |
| Board Copy | .9521 |
| Copy Span | .8393 |

According to Murphy and Davidshofer (1988) scores of .95 indicate high reliability while scores of .83 would be in the moderate range. Thus the correlations in Table 4 give us confidence that the further statistical analyses of
scores are meaningful exercises as there is good consistency in handwriting speed and copy span.

Internal. Correlations among the tests were all significant at the p.<. 01 level (see Table 5). It will be noted that there is a high degree of correlation between alphabet copy tasks with lower correlations for other tasks.

Table 5. Internal Correlations Among Tests

|  | Symbols | Nonsense | Desk | Board | Copy Span |
| :---: | :---: | :---: | :---: | :---: | :---: |
| X's | . 6130 | . 6922 | . 6798 | . 6951 | . 4545 |
| Symbols |  | . 7431 | . 7336 | . 7071 | . 4745 |
| Nonsense |  |  | . 9342 | . 9097 | . 6186 |
| Desk |  |  |  | . 9334 | . 6545 |
| Board |  |  |  |  | . 6664 |

## Copy Speed

A Manova Profile Analysis (comparing 5 speed tasks by 7 grades including how the profiles for each grade varied) showed that the students of different grades differed significantly, $F(6,385)=127.42, \mathrm{p} .<.001$, in speed, and that within each grade there was a significant difference in speed on the various tasks, Mult. $F(4,1540)$ $=1126.15$, p.<.001, as predicted. There was also a significant grade by task interaction, Mult.F(24, 1540) = $22.54, \mathrm{p} .<.001$, which indicated that the grades did not vary in the same way from task to task.

The anticipated hierarchy of speed tasks (X's, desk, board, nonsense and symbol) held for grades 2 to 4 only. Symbols were slowest for all grades as predicted, but X's went from the fastest in grades 2 to 4 , to the second slowest in grades 6-8. Grade 5 appeared to be a transition year (see Table 6).

## Table 6. Order of Speed on Tasks by Grade*

| Grade | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| X's | 1 | 1 | 1 | 3 | 4 | 4 | 4 |
| Desk | 2 | 2 | 2 | 1 | 1 | 1 | 1 |
| Board | 3 | 3 | 3 | 2 | 2 | 2 | 2 |
| Nonsense | 4 | 4 | 4 | 4 | 3 | 3 | 3 |
| Symbol | 5 | 5 | 5 | 5 | 5 | 5 | 5 |
| * 1=fastest |  |  |  |  |  |  |  |

A Manova (task by sex) of the entire sample showed no sex difference. A Manova (task by style by sex) was done on all subjects over grade 3 (because cursive is introduced in grade 3 in the area where this study was conducted). This second analysis showed no effect of writing style (manuscript vs. cursive). It was significant however for sex in the older subgroup, Pillais, $F(5,256)=4.15, \mathrm{p}<.001$. Univariate tests showed the sex effect to be present on the nonsense, $F(1,256)=9.98, \mathrm{p} .<.002$, desk, $F(1,256)=8.24, \mathrm{p} .<.004$, and board copy, $F(1,256)=7.17, p .<.008$, tasks only.

Table 7. Correlation of Speed and Errors

| Task | Pearson's r | $\mathrm{p.}^{*}$ |
| :--- | :---: | :---: |
| $\mathrm{X}^{\prime} \mathrm{s}$ | .2552 | .01 |
| Symbol | .2811 | .01 |
| Nonsense | .1459 | .01 |
| Desk | .2364 | .01 |
| Board | .1213 | .05 |

* Probabilities are not Bonferoni corrected.

The number of errors made had a significant positive correlation with the speed scored on the various tasks. As can be seen from Table 7, however, such correlations were low. A Manova analysis done on corrected scores (speed - errors) showed the same patterns as that done on the uncorrected scores. Since uncorrected scores more closely resemble classroom conditions, these were used for means and interpretation. No significant effect of eye or hand dominance or of writing posture was detected.

A one-tailed paired $T$-test comparing the grade 5 through 8 pilot students on the desk task and the low readability level copy task was significant in the expected direction, $\underline{t}(27)=-1.96, \mathrm{p} .<.05$. Students were faster on the easier copy.

Copy speed on the board task was positively correlated with copy span, $\underline{r}=$.6664, $p .<.01$. A paired
t-test showed the students to be faster on the desk task than the board task, $t, 391=10.28, \mathrm{p} .<.001$, as predicted. The student's location (front or back) of the classroom was not significant in the board or copy span measures.

Investigation with a stepwise multiple regression showed motor speed (X's) to be the most important factor after age or grade on all other speed tests [symbols, Beta=. 364113 ; nonsense, Beta=.347275; desk, Beta=.327312; board, Beta=.369148].

## Copy Span

An Anova comparing the grades on copy span showed that there was a significant difference between them, $F(6,380)=45.79, p .<.001$. There was no significant difference between sexes on copy span. A Manova comparing all students whose copy span was below a $z$-score of -1.00 for their respective grades with those whose copy span zscore was over +1.00 on their performance in the nonsense, desk and board copy showed that copy span was a significant factor in copy speed (with motor speed used as a covariate) on both the desk, $F(1,113)=8.27$, p. $<.005$, and board copy, $F(1,113)=12.99, \mathrm{p} .<.001$, tasks. It was not significant in the nonsense task.

## Discussion

## Reliability

Test Retest. The test-retest reliability of all the measures of handwriting copy speed used was higher after 26 days than Mojet (1991) found after two months. A higher correlation is to be expected, not only because correlations generally decline with time, but because, as the results show, there is a strong effect of grade on speed. Thus, after two months, the continuing educational experience should have caused more variation in Mojet's subjects. Test-retest reliabilities in the ranges shown in Table 1 are generally considered acceptable (Murphy \& Davidshofer, 1988). Copy span testretest reliability after 14 days was in the moderate range.

Internal. The internal reliability of the CSAS appears to be good. The alphabet tasks are all highly correlated. The correlations are lower between the X's (motor) and the Copy Span task though these are still significant. This significant correlation may be a result of the effect of maturation on both tasks.

## Copy Speed

The findings that speed increases with age and grade
are consistent with Hildreth's (1947) assertion that maturation is a major factor in handwriting speed. Maturation, however, is not sufficient to explain the shift in relative ranking of the speed tasks from X's being fastest in young children to meaningful copying using known words presented as desk copy being fastest for older children. This shift would be more easily explained in terms of a practice effect making the graphic motor pattern stronger or more easily accessible. The highly significant effect of the motor speed task on all other speed tasks indicates that motor speed is a very important factor. This effect is present even when the effect of age is removed. Keele and Hawkins (1982) found the rate of repetitive activity to be common across muscle groups so it would appear to perhaps be a genetic factor. If it is a natural, inborn factor, then it would imply that some students just cannot write speedily no matter how hard they try. Studies to determine if slow writers can be brought up to the level of fast writers by extra practice, perhaps with special treats for achievement, might be useful. If such a plan succeeded, schools could use it to help slower students improve. If it was shown that it had little effect, then
expectations and pressures on students with slower motor speed could be reduced. An individual measure of motor speed preferably using a different muscle group would help to ensure that students truly fit the description "slow motor speed". While the student's location in the classroom was not a significant factor in the board or copy span tasks, there was a significant difference in the speed of copying depending on whether the materials were presented on the desk or on the board. Board copy was slower as predicted. This was likely because of the added effort required to focus on a small area within a much larger space at some distance.

Easier material was copied faster than more difficult material as predicted. This may have been because the copy span is related to the information burden of the material as Rothkopf (1980) showed. In this study an attempt was made to keep the information burden constant across grades on desk and board tasks by using materials one level lower than recommended by the GORT (Robinson, 1963) for the grade. Unfortunately no information was available on the reading levels of our students. Thus it is possible that those with high
scores on our speed tests were reading at higher than grade levels, and those with lower scores were reading at lower than grade levels. Love (1965), Jackson (1970), and May and Brannin (1984) found a relationship between greater speed and higher intelligence. It may be that a relationship between speed and intelligence is mediated by the reading level of the student and the difficulty level of the material. This hypothesis would be consistent with the findings of Whitehouse (1983) and Sovik, Arntzen \& Thygesen (1987), that dyslexics write slower than "normals".

The problem of the difficulty level of the material is one that surfaces throughout the literature, and seldom appears to have been considered. The studies reviewed earlier that described the test material, apparently all used the same material on all grades tested. In some cases the students were given a time of practice with the material. It would appear that the practice effects helped to overcome the problem of difficulty level. Material difficulty level is clearly an area that needs much more consideration in future research.

The number of errors on each task did correlate
positively with the speed on that task. However, the percentage of students making more than five errors on a test was only $7.3 \%$ on the board copy. Other tests had fewer with the lowest being $2.8 \%$ on the nonsense syllable test. Some students did seem to focus only on how fast they could write. One grade 8 student was observed to write the board copy task with his eyes focused entirely on the board, making no effort to check his placement on the paper. Amazingly, his copy was largely decipherable.

Of our 425 students, 54 were left handed, 25 using the inverted posture. There were also six students who wrote with right handed inverted posture. In agreement with the findings of Auzias (1973) and Herron (1980), this study found no significant effect of handedness on speed. Checks of the effects of direction of paper tilt and mixed eye-hand dominance failed to find any significant effect on speed either.

Cursive style was not found to be any faster than manuscript style in this study when the grade 2 and 3 students were removed. This finding is in agreement with Jackson's (1970) findings. Students were allowed to choose whichever style they preferred. Those who switched styles on different tasks [n=30] were removed
from analyses involving style. In grade 2 all students used manuscript. A few students in Grade 3 chose cursive, but since they were just being introduced to cursive style writing, grade 3 was not included in the analysis of style effects. The lack of difference between styles may support the effect of practice on speed. Whichever style is preferred and used most may be faster.

Sex did not have a significant effect when the entire population was considered. The analysis using just the grade 4 and older students did show a significant effect of sex for those tasks which involved the alphabet letters. This conflicts with the findings of Jackson (1970) who was working with grade 5 and 6 students using copy involving alphabet letters, but agrees with Burt (1921, quoted in Bailey, 1988), Groff (1963, in Andersen, 1965), Klein (1979) and Ziviani (1984) who found females faster.

It is interesting to note that males and females were not significantly different in motor speed in this study. This finding agrees with Judd, Siders, Siders, and Atkins (1986). However they found boys slower at symbol copying than girls, whereas this study found no
significant difference. This apparent contradiction may be because older students were included in the present study. When we examine the means in this study, we find that the boys were slower at symbol copying as Judd et.al. reported, but only through grade 6. They were faster in grades 7 and 8.

When males and females do not differ significantly on motor speed, the difference in copy speed evident in this study especially for alphabet related tasks needs more research. Perhaps the females were more advanced in reading and thus the task was easier for them. Or perhaps the commonly observed preference of girls to "play school" or write letters to pen pals may lead to a significantly increased amount of practice in alphabet usage by the time they reach grade 4. This sex difference is an area for future research that could have important instructional implications.

Another area for investigation is the amount of discrepancy between motor speed and speed on desk or board copy in individual students that would fall within the normal range. Perhaps there are students who are normal in motor speed measures but slow in other measures. If such students were identified perhaps a
test of handwriting speed would be a quick and inexpensive classroom measure for determining which students need referral for further learning ability assessment.

The speed hierarchy was only as predicted for the early grades (2-4). Grade 5 appears to be a transitional year after which a different pattern emerges in the higher grades (6-8). As predicted, copying unfamiliar symbols was the slowest task for all grades. If one believes that the brain creates graphic motor patterns when exposed to a copying task and saves these for future use (Margolin, 1991), then perhaps symbols are slowest because, in contrast to alphabet letters, graphic motor patterns have not yet been created for them.

Contrasting the younger grades with the older on the other four tasks one wonders why there is a shift. The X's task is largely motor speed. The nonsense task uses alphabet without meaning. The desk task uses alphabet with known words and meaningful arrangement. The board task mimics the desk task, but with a distance variable. It seems that while motor speed is initially most important, meaning and then familiarity with the alphabet become increasingly so as a student progresses through
the grades. When one compares the mechanics of making three "X's" as opposed to writing the word "the" one finds that the tasks can be broken into the same number of strokes. For some writers "the" may have more changes of direction. Yet three "X's" seems to require more time. It is possible that a physical motor speed ceiling effect is partly responsible. Figures 1, 2, and 3 (see Appendix E) all show that there seems to be a period from grade 3 to grade 6 when there is almost no increase in speed on the "X's" task. The speed then increases again in grade 7 and 8 for both sexes. In the older grades it would appear that the effect of practice with the alphabet overtakes the effect of motor speed alone, as students have much more practice using words of mixed letters than just writing the letter "X" over and over. Perhaps this practice effect is related to a more defined graphic motor pattern or to a more frequently travelled path to the pattern. In either case, it is clear that those items which are more frequently encountered are written faster. This finding reemphasizes the need for practice to attain speed. As stated earlier, the additional distance variable in the board task likely interferes with perception of the image to be copied.

The additional focusing time thus slows the whole task.

## Copy Span

Copy span increased with age and grade. The words used for the copy span task were all very easy words that even the grade 2 's should have encountered in their reading. Hulme, Thomson, Muir and Lawrence (1984) showed a strong positive relationship between articulation speed and memory span which increased with age. Perhaps some of this increasing articulation speed and span is responsible for the increased copy span as age increases. However, here again the effect of practice might be an important factor. Older students have been using these words in their reading and writing many more times than younger students making it easier for them to identify them during the 5 second display period. If they could more quickly identify larger units by grouping letters into words, then they would be more likely to copy by words or phrases rather than by letter as Bradley (1983) described. Older students might also have had the advantage of being able to use phonological rehearsal to greater effect as suggested by Hulme et.al. (1984). A alternative explanation might be that younger students, having a slower motor speed, may have suffered more trace
decay while writing the first word or two because more time had elapsed, and thus have forgotten more. Faster students might be able to get more on paper before the trace fades. Simner (1991) suggested that slower writers may have a trace fading problem. Research to discover what determines copy span would be difficult but useful. Whatever the mechanism determining our measure of copy span, it had a significant effect on copy speed on the board task. It is to be expected that any span effect on speed would be magnified in a task where perception takes more effort. Each look back at the copy would take more time and thus slow the overall effort. In light of the findings that span increases from grade to grade, it would be interesting to see if attempts to teach students to increase their span would be successful. Perhaps teaching younger students to use phonological rehearsal strategies with visual material would increase their span.

The findings of this study support the CSAS as a useful tool for handwriting research. Clearly any test of writing speed must use models that are appropriate for the grade level of the student being tested. Use of only one model for several grades may artificially inflate the
scores of the higher grades or depress those of grades lower than the level of the copy material.

Use of a test such as the CSAS allows one to gather a sample of different kinds of copying ability. The norms and percentile tables provided (see Appendices $F$ and G) are designed to be useful in assisting the professional to diagnose if a student has a writing problem or not. Sometimes an average student in a class of fast writers is unfairly labelled as "slow". If a student has a problem, then the subtests may help to identify the type of problem and suggest remedial action. Various combinations of abilities on subtests may help teachers to identify a student's problem. A combination of a high motor speed (X's) percentile ranking with low alphabet copy scores (nonsense, desk, board) may suggest that a student needs to improve reading skills or may respond more quickly to extra practice. Low scores on motor and alphabet tasks may suggest that a student has a slow motor speed and may not respond as quickly to practice. A student who does well on the desk task, but who is considerably slower on the board task than average, may have a problem with vision or spatial awareness. A student who does poorly on the copy span
task may have a memory problem or may need to be taught how to organize perceptions for easier recall. Comparisons are also possible between meaningful and nonmeaningful copy and between a task requiring visual memory (symbols) and one which can be rehearsed verbally (copy span). Research is needed to verify these possibilities.

The findings of this study that sex is a significant factor from grade 4 onward suggested the need for separate norms for males and females. However, because dividing the sample by sex led to some small cell sizes norms are also provided for the combined sample. Grade norms will most likely be more useful for screening purposes, but if a student is above or below the average age for their grade, then age norms should be used instead.

Summary and Conclusions

Copy speed and span both increase with age and grade. The relative speed of tasks varies with grade. The lower grades went from $X$ 's (motor speed) as the fastest task through desk, board, nonsense and symbol.

Higher grades also were slowest at the symbol task, but had desk as the fastest, with board, nonsense and X's (motor speed) following. While some of this is likely a factor of maturation, it was thought that there is also an effect of practice and thus the enhancement of graphic motor program formation and development of new strategies for recalling more text with each look.

Other factors that seem to be involved with copy speed are the distance of the copy, the basic motor speed of the individual, the level of difficulty of the copy material, and, in the higher grades with alphabet related material, sex. Copy span is positively related to copy speed and increases with grade and age.

Further research is needed to determine the cause of speed differences between sexes in the higher grades. Males may write slower because of less informal practice or lower reading levels.

Copy span may be a function of reading level. Research needs to determine if lower copy speed is a function of shorter copy span, or if the measure of copy span is distorted by the lower copy speed.

Children who are slower in copy speed need help. Perhaps speed training would help with increasing speed
in the regular class work in a way similar to an athlete's training for a competition. Perhaps an improvement in motor speed or copy span can be trained. If so, perhaps computer games manufacturers could be persuaded to create games using copy span and handwriting tasks that would be fun and beneficial for slower students. If it can be determined that handwriting copy speed is related to general learning ability then we need to know how it is related. Perhaps the lack of ability slows the writing, or maybe it is the slow writing that causes a deficit in learning. Perhaps a child's need for learning assessment by psychologists can be accurately determined by teachers using a test such as this as a screening device in the classroom.

The Copy Speed and Span Test provides a method of controlling the difficulty level of the copy model. It also provides a means for determining differences between motor speed, meaningful and nonmeaningful copy, near versus distant copy and ability to retain visual material (symbols) versus words which could be pronounced. The norms obtained from this study may be a starting point for further research in this area. Teachers and psychometrists may wish to use this information to devise
new strategies for dealing with children who seem to be slower than their classmates in getting material copied.

## Low Reading Level Desk Copy

The old man sat on the green grass. He could see a little brown fox on the hill. It was playing with five more little foxes. They all ran around and jumped at each other. Their mother just sat under a tree to see that they didn't get hurt. After a long time they went into their den to go to sleep. Then the old man got up and went home to wash his hands and eat supper.

Appendix C: Consent Forms

## Dear Parent:

In the next few weeks a study will be done at school. The purpose of the study is to find the average speed at which children of a certain age or grade can copy different types of written material. Students will be tested as a class during regular class time for about 20 minutes. Three classes will repeat the tasks later to see if rates are similar over time.

Your child's work will not have any name on it so all will be confidential.

Participation is completely voluntary. We believe the results will create a standard by which parents and teachers can later determine how a child is doing.

If you wish to give permission, please sign the attached form. If you DO NOT want your child to participate, please indicate this by signing the appropriate space on the form. Please return the Consent Form by

If you have any questions, or wish a copy of the final results, please feel free to call the number listed below. Thank you.

```
                    Sincerely,
                    Mrs. W. Bauman
                        343-8110 (Ask for Psychology)
\overline{PLEASE}

Copy Speed 62

## Dear Parent:

In the next few weeks we plan to do a study at school. We would like to test students in their regular class for about 20 minutes. Students will be given activities measuring their muscle speed, ability to copy things that require them to remember what they see or what they can say to themselves, and ability to copy simple material such as they would find in a textbook or on the board. The purpose is to find how quickly children of each age or grade can copy different types of written material and what abilities are the most helpful in copying.

Your child's work will NOT have any name on it. No child will know what score they obtained. Teachers will only get a report where all scores have been added together. Participation is voluntary.

It is important in a study like this to have as many students as possible take part. If only the fast or slow students participate, then teachers will have too high or low expectations of other children in future.

Obtaining this information will enable us to create a modern standard to help teachers and parents know if a particular child needs extra help and practice. It will also help the child to know when he/she has improved to the level of most children in his/her grade.

Please sign this form to give your child permission to be a part of it.

If you DO NOT want your child to participate, please indicate this by signing the appropriate space on the form.

Either way, please return the form this week.
If you have questions, or wish a summary of the final results, please feel free to call the number listed below. Thank you.

Sincerely,

Mrs. W. Bauman
343-8110 (Ask for Psychology)

PLEASE DETACH AND RETURN TO SCHOOL BEFORE FRIDAY.
$\square$ I give permission for my son/daughter $\qquad$ (full name)
to participate in the copy speed study.
$\square$ I DO NOT give permission for my son/daughter (full name)
to participate in the study described.

Appendix D: Instructions for Tasks

WE WANT TO SEE HOW MUCH YOU CAN COPY IN A SET TIME. WE MADE THE TASKS LONG SO NO ONE WILL BE ABLE TO FINISH. DO NOT START UNTIL I SAY "GO" AND BE SURE TO STOP AS SOON AS I SAY "STOP", EVEN IF YOU ARE IN THE MIDDLE OF A WORD. ON SOME OF THE TASKS YOU WILL BE ABLE TO CHOOSE WHETHER YOU WISH TO PRINT OR WRITE. DO WHAT IS EASIEST FOR YOU. IF YOU MAKE A MISTAKE, DO NOT ERASE. JUST KEEP WORKING. (Allow questions (Q) after each set of instructions. Clarify as much as needed.)

1. FIND NUMBER 1 ON YOUR ANSWER SHEET ON THE FRONT PAGE. JUST BELOW IT YOU WILL SEE MANY SQUARES. WHEN I SAY GO, I WANT YOU TO PUT AN X (NOT A +) IN EACH BOX AS QUICKLY AS YOU CAN. KEEP GOING UNTIL I SAY STOP. YOU WILL HAVE ONE MINUTE. (Q) READY? GO.
2. NOW TURN THE PAGE. YOU WILL SEE MANY BOXES. THE TOP ONES HAVE A FIGURE IN THEM AND THE BOTTOM ONES ARE EMPTY. YOU ARE TO LOOK AT THE FIGURE IN THE TOP BOX AND MAKE ONE LIKE IT IN THE BOTTOM BOX. WHEN I SAY "GO" START AT THE FIRST BOX AND WORK AS QUICKLY AS YOU CAN ACROSS THE ROW WITHOUT SKIPPING ANY. WHEN YOU FINISH ONE ROW GO ON TO THE NEXT UNTIL I TELL YOU TO STOP. YOU WILL HAVE ONE MINUTE. (Q) READY? GO.
3. FIND 3 ON YOUR ANSWER BOOKLET. YOU WILL SEE SOME EMPTY LINES. NOW LOOK AT THE CARD YOU HAVE ON YOUR DESK. IT HAS MANY NONSENSE WORDS ON IT. THIS TIME WHEN I SAY "GO" YOU ARE TO COPY AS MANY OF THE NONSENSE WORDS AS YOU CAN ONTO THE LINES BY THE 3 ON YOUR ANSWER SHEET. WORK AS QUICKLY AS YOU CAN, BUT I MUST BE ABLE TO READ IT. YOU WILL HAVE ONE MINUTE. (Q) READY? GO.
4. FIND 4 ON YOUR ANSWER BOOKLET. AGAIN YOU WILL SEE SOME EMPTY LINES. WHEN I SAY GO, YOU ARE TO COPY THE STORY YOU WILL SEE ON THE SCREEN. WORK AS QUICKLY AS YOU CAN, BUT I MUST BE ABLE TO READ IT. YOU WILL HAVE TWO MINUTES. (Q) CAN EVERYONE SEE THE SCREEN? READY? (Turn on overhead) GO .
5. FIND 5 ON THE BACK PAGE OF YOUR ANSWER SHEET. THERE ARE SOME EMPTY LINES. DO NOT TURN THE CARD OVER UNTIL I TELL YOU. WHEN I SAY "GO", YOU WILL HAVE TWO MINUTES TO COPY THE STORY FROM THE CARD ON YOUR DESK. WORK AS QUICKLY AS YOU CAN BUT I MUST BE ABLE TO READ IT. (Q) NOW TURN THE CARD RIGHT SIDE UP. READY? GO.
6. I AM GOING TO SHOW YOU SOME LINES OF WORDS ON THE SCREEN. THEY ARE ALL WORDS THAT YOU HAVE SEEN IN YOUR READING. I WILL SHOW THEM TO YOU FOR ONLY 5 SECONDS SO YOU MUST LOOK CAREFULLY ALL THE TIME. THEN I WILL COVER THEM, AND YOU WILL WRITE AS MUCH AS YOU CAN OF WHAT YOU SAW. DON'T WORRY IF YOU ARE UNSURE OF HOW TO SPELL THE WORD. JUST WRITE DOWN AS MUCH AS YOU CAN. THIS IS TO SEE HOW MUCH YOU REMEMBER SO DO NOT LOOK AT YOUR FRIEND'S PAPER. DO NOT BEGIN WRITING UNTIL I COVER THE SENTENCE AND SAY "GO". (Q) CAN EVERYONE SEE THE SCREEN? NOW LOOK CAREFULLY. (Turn on overhead.
After 5 seconds cover sample.) GO. (Repeat NOW LOOK CAREFULLY.....GO for each sentence) Wait for everyone to finish.
(Before showing the first two line sample say) this TIME YOU WILL SEE TWO LINES OF WORDS. MOST PEOPLE CAN NOT EVEN READ THEM ALL IN 5 SECONDS. DON'T WORRY ABOUT IT. JUST REMEMBER AS MANY AS YOU CAN.

EXTRA PARAGRAPH FOR PILOT
YOU HAVE AN EXTRA PIECE OF PAPER ON YOUR DESK. IT HAS A NUMBER ON IT THE SAME AS THE NUMBER ON YOUR ANSWER SHEET. WHEN I SAY GO, YOU ARE TO COPY THE STORY FROM THIS PAPER (show) ONTO THAT PAPER. WORK AS QUICKLY AS YOU CAN, BUT I MUST BE ABLE TO READ IT. YOU WILL HAVE TWO MINUTES. IF YOU FINISH EARLY, TRY TO COPY THE FIRST PART AGAIN. (Q) READY? GO.
